LUDF Focus Day

LUDF Dry-off Plan

LUDF Planned Start of Calving 27 July.

Table 1.

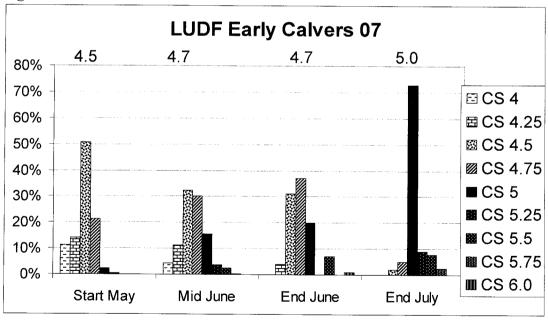

R3yr	Cow	Dry days	LUDF	LUDF
C.S group	C.S group	required *	Early	Late
			Calvers	Calvers
Below 4.0	Below 3.5	120	28 Mar	19 Apr
4.0 - 4.4	3.5 - 3.9	90	28 April	19 May
4.5 - 4.9	4.0 - 4.4	60	27 May	18 June
5.0 plus	4.5 plus	50	1 June	21 June

- refer to the Dexcel Condition Scoring Made Easy pg 32.
- Early calvers are due to calve in the first three weeks (about 70% of the herd)
- There dates are the latest that these groups should be dried off.

Cows below Condition Score 4.0 were put onto OAD in FEBRUARY and because they have put on weight and condition score, we have no cows to be dried off before the 28 April.

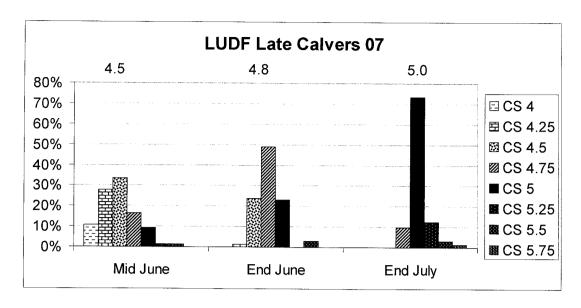

Condition Score of the herd at Start of Calving.

Fig 1

The 80 thinnest early calvers were dried off in early May. These cows were grazed off farm and suffered ryegrass staggers. These cows have struggled to put on weight over winter and have ended up at a condition score between 4.5 and 4.75. The other fatter early calving cows have easily reached a condition score of above 5.

Fig 2.

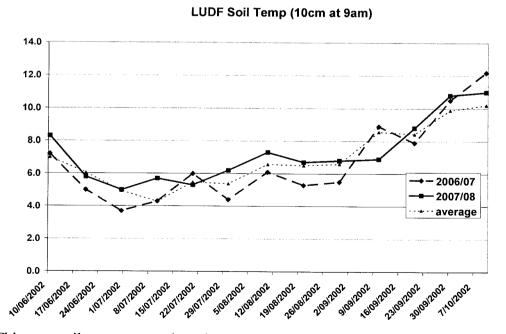

The late calving cows were dried off because of lack of cover on farm and had plenty of time to get back up to the target condition score. In early July the cows in this mob who where till below score 5 would not calve until September and so still had plenty of time to get above 5.

Take home message.

The Dexcel recommendations for when to dry off cows based on expected calving date and condition score are correct and the job has to be well done to achieve the target condition score.

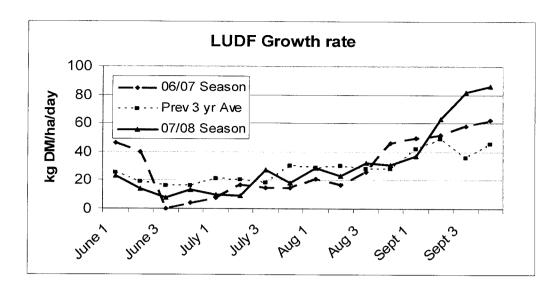

Early lightest cows didn't make it because their weight gain was compromised by ryegrass staggers. The late calving cows were dried of earlier than required and they have easily reached the target condition score.

Conditions this Season

This year soil temperatures have been warmer than average compare with last year when they were colder than average.

Fig 4.

Pasture growth has consistently been better than last year but was below the average for the farm. This is surprising given that soil temperatures have been higher than average. Total growth is about 0.5t/ha or 80t behind an average year.

We have two factors that may have combined to explain this:

- a) The long pre-grazing covers through the autumn leading to tiller death and a more open pasture coming into the winter
- b) Farm had become Nitrogen deficient.

In late summer we lengthened the round out to between 35 to 40 days. Growth rates were unusually high and so pre-grazing pasture covers were regularly over 4000 kgs DM /ha. At these covers, canopy closure had occurred and the pastures became yellow at the base. We noted in the autumn that re-growth was much slower of these paddocks than the average for the farm from the same week. We also observed that these same paddocks had more open pastures that others consistently grazed at lower covers which indicate that tiller death may have had occurred.

The farm had its last N applications last season (other than to effluent areas) between end of February and early April. The suspicion was that the lower growth rates was because of low N availability and this was being visually confirmed by the clumpy nature of the pasture where the manure and urine areas were growing well and the areas between have poor growth and were yellow and nitrogen deficient.

Econ N was applied in May and it works to improve pasture yield by preventing the N in the manure and urine areas from being leached. This also helps to explain why there was such a difference between the manure/urine areas and the non manure/urine areas.

Take home messages from autumn management

1) While it was profitable to lengthen autumn rounds to above 35 days and not have to feed out silage, in the longer term there was a cost in pasture density and yield. This suggests that on LUDF round length of 30 to 35 days in the autumn with pre-grazing covers of up to 22 clicks (3500 kg DM/ha) is a better compromise because of less ongoing negative affect on growth rates.

2) Last N application should extend into early May when possible to promote early winter growth.

The Key management tools from dry off to balance date

A feed budget (updated weekly) and simple graphs track how the farm is going compared to budget.

Fig 5.

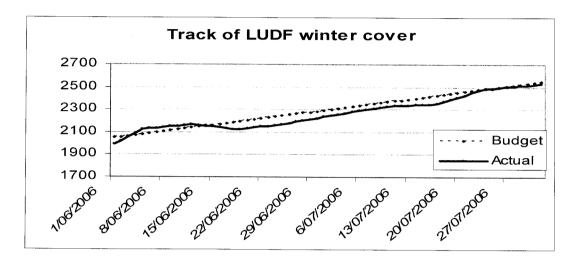

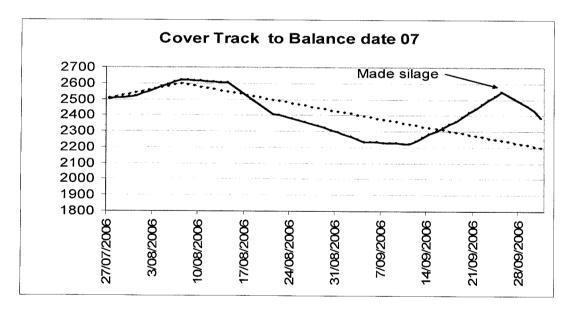

Fig 6.

The target lines on these graphs are generated from a feed budget. The critical starting point is the cover required at balance date. We then work backward putting in expected growth rates, calving spread and cow numbers on farm for each week. This calculates the second critical cover target which is the average cover required on farm at the start of calving. Again back calculating from this with winter growth rates and cow demand on the milking platform and we end up at the third critical average farm cover which is the cover at dry off date – nominally the 1st June.

Refer Appendix 1. LUDF Winter feed budget.

This winter we grazed the milking platform harder than any previous season.

- 1. We dried off on the milking platform. In previous years much of this was done off farm. Several paddocks were grazed down to 1000 kg DM /ha.
- 2. When possible the R2yr heifers were grazed on the platform over the winter. These animals started winter at condition score 5.5 so were only fed maintenance and again they left residuals between 1000 and 1200 kg DM /ha.
- 3. There was no feed left on the East Block runoff and so the first 500 springers were grazed on the milking platform, leaving residuals of about 1200 kg DM/ha.

The combined result was that over the winter about 1/3 of the farm was grazed to low residuals and some of these took up to 40 days just to get back to a milking cow residual of 1500 kg DM/ha.

On the other hand ground conditions have generally been firmer and so pugging risk lower. At times the cows have still "messed" the pasture which has left a small number of paddocks with higher residuals than target. These have been fixed by the cows during the second round.

Changes for next autumn/winter

- 1) Cow being dried off will be moved off platform earlier.
- 2) Only early thin cows will be kept on the milking platform over winter.
- 3) Springer mobs will be kept off the milking platform as much as possible.

Key take home message

- 1) Do a feed budget to work out the three critical farm average pasture cover targets.
- 2) Walk the farm regularly and update the feed budgets with new covers, growth rates and cow numbers.
- 3) Use a graph to monitor the progress to achieving these critical cover targets.
- 4) Plan to keep residuals on milking platform of between 6 & 7 RPM clicks (1350 1500 kg DM /ha)

This year's management from 2 weeks before the planned start of calving.

- 1. Heifers were already on the milking platform being trained to the cow shed, walk over weighing, automatic drafting and automatic teat spraying.
- 2. The first cows that were bagging up were drafted out of the early calving wintering mob and returned to the milking platform. This continued up to several times a week until all the cows were walked home from winter grazing.
- 3. Springing cows feed allocation was restricted to 10 kg DM/cow/day. This was done because pasture covers were below target.
- 4. The springers were brought to the shed to draft out calved cows and to get teat sprayed. They were stood off when soil conditions were soft and kept on the yard during the day for about 20 days during August. They were calved in the milking yards if required.

Nitrogen Fertilizer Applications

The decision was made to apply N fertilizer earlier this season because of the N deficiency noticed over the winter. This was done once soil temperatures in July were over 5 °C. Twenty six kg N/ha was applied over half of the farm. It was followed up with an application of 40 kg N/ha following the cows during the first grazing round.

Pasture allocation.

This was strictly rationed according to the following plan. Any intake deficits were filled with grass silage.

Table 2.

For our First Round planner of 60 days starting 24 July includes the milking platform area plus the 18 ha East block.

Week	Date (start of week)	Milking cows (Avg)	Area grazed for week by milkers	Average Dry cows (home)	Area grazed for week by dry cows	Total area to be used for week	Actual area used for the week
1	24 Jul	157	2.2	118	1.7	3.9	3.9
2	31 Jul	267	4.5	493	4.1	8.6	7
3	7 Aug	377	9.3	383	5.9	14.2	16
4	14 Aug	457	14.6	288	5	19.6	21.4
5	21 Aug	517	17	218	3.8	23.5	23
6	28 Aug	567	19	163	2.9	25.2	24.3
7	04 Sept	607	24.7	118	2.1	30.7	23.03
8	11 Sept	632	30.4	86	1.5	31.9	19
9	18 Sept	657	38.3	61	1.1	39.4	39.25

The second half of our calving slowed down more than expected. This allowed us to use less area than originally planned and control the size of the deficit in pasture cover we faced.

Table 3.

Tota	al	162	530	692		

In the first week most of the calved cows are heifers and several research studies show that heifers do not reach this level of intakes until several weeks after calving. Cows calved at this time have been able to access more than 12 kg DM because the heifers will not have eaten their allocation.

Table 4.

Intakes for the herd in table 4 rise more slowly than the weekly increase in intakes in table 3 because the herd is a mix of cows differ in how long since they have calved.

Fig 7.

Calved Cow intakes on a herd basis

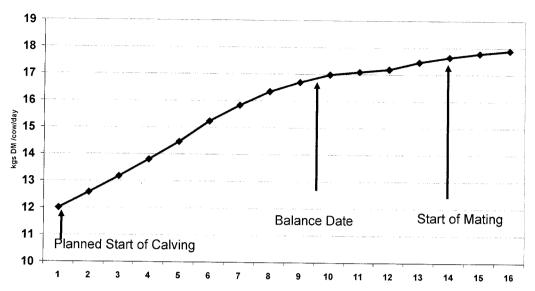

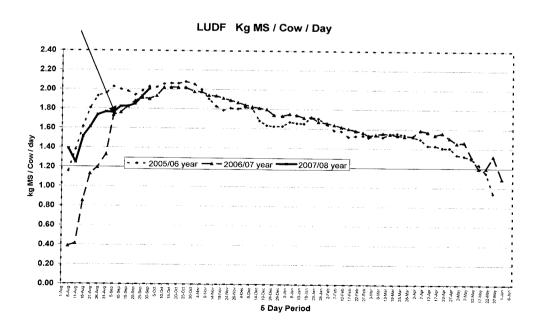

Fig 7 shows that the herd is on a rising plane of nutrition especially given that less of their allocation is high quality silage and more of higher quality pasture that has an ME above 12.

The preferred position for LUDF is to have all the allowance as pasture. This is because pasture is the highest quality, cheapest feed we can get and it takes the least infrastructure and people time to feed to the cows. This year we were not able to achieve this until late September and milk production has been reduced as a result. We were feeding between 2 and 5 kg DM grass silage/cow/day. See Data sheets.

The Results **Production**

Fig 8

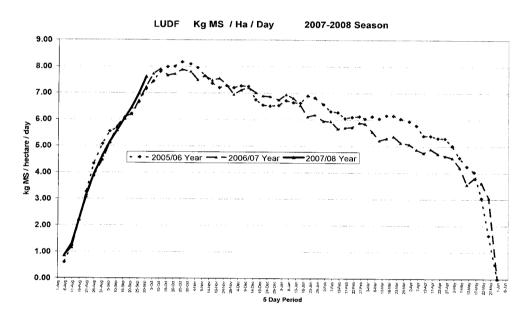

The pointer highlights the gap in /cow /day production that has resulted from not having enough high quality grass and having to support cow intakes with lesser but good quality grass silage.

Peak per cow production has still reached over 2 kg MS /cow/day despite the first half of the calved herd being milked OAD for up to 3 weeks at the start the lactation, all later colostrum cows being milked OAD and with the feeding levels allocated in table 4 previously.

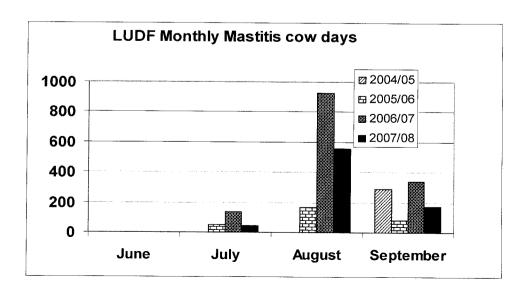

Supplements fed to the 1st October were 87 kg DM /cow compared with 62 kg DM /cow last year. The average ME of the grass silage fed was 10.8 ME.

For next season the start of calving will be put back from the 27 July back to the 1 August. This will line up early season demand better with pasture supply without requiring the excessive pasture cover currently required at the planned start of calving.

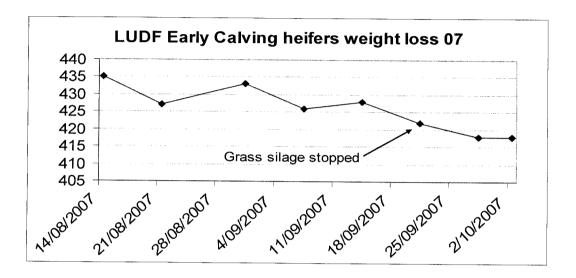

Milk solids /ha is 0.2% behind the farm previous record year of 1772 kg MS /ha and 6% behind our budget target of 1830 kg MS /ha.

Animal Health

The heifers were teat sprayed for a much shorter time that planned before the start of calving. They were only teat sprayed about 3 times in the two weeks before calving. The early season mastitis occurred in the newly calved cows and was less than last year but still more than previous drier weather winters. Fifty percent of the mastitis was in the first calvers and this percentage is the same as last year. The mastitis cases in the heifers have cured well but three heifers have lost a quarter as a result.

Last winter was the second year that we have unsuccessfully attempted to implement a regular teat spraying plan for the first calver heifers. We are going to have to consider another option, probably teat seal.

These heifers have lost about 17 kg of live weight which is just over half a condition score. This is normal and shows that these animals were sufficiently well fed after calving.

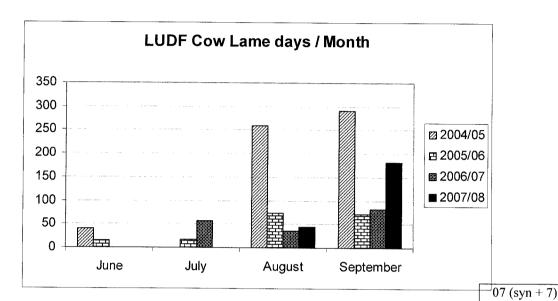

The herd average condition score at the end of September is 4.4. This is almost the same as the condition score of the herd at the same time last year.

Cow Deaths out of 704 to calve

Month	Reason	06/07	07/08
June	Heart failure	0	1
July	Accidental	2	0
	Milk Fever	2	0
August	Accidental	3	0
	Bloat	1	0
	Other	1	2
	Milk fever	0	1
September	Liver problems	2	0
	Bloat	3	0
	Milk fever	0	1
October (to date)	Bloat	1	0
	Milk fever	0	1
	Johnnes	0	1
Total		15	7

The 8 less deaths so far this year represent a potential profit improvement of over \$12,000 so far. The 7 deaths represent a wastage rate of less than 1% on the total cows wintered. This is significantly better than typical for large herds.

The total number of assisted calvings was 15. Nine of these were in the heifers (mostly due to abnormal presentation) and 6 were in the mature herd.

Most of the lame cows this season also had been lame last season.

Wk 11	1	0	1	1
Total calved	104	143	175	187

The simple two prostaglandin injection synchrony program (see attached protocol) with our R2yr heifers continues to give us excellent results with 88% calving before the end of the 4th week of calving of the main herd.

This year the added bonus was that we gained 45 replacement heifer calves from this. Last year we only got 15 replacement heifer calves. The difference was simply more favourable ratio of heifer to bull calves this year.

LUDF Calving /Mating data comparison

Season	02/03	03/04	04/05	05/06	06/07	07/08
Days to mid (all herd)		22	23	14	12	16
Days to mid (cows only)		22	23	22	16	22
4 wk calving rate %	64	63	61	69	76	66
% still to calve 1 month PSM	14	17	12	12.6	4	7
% treated as Anoestrus		36.7	24.3	14.5	17	
% incalf at 12 weeks	84	83	79.5	84	86	

Last years wet difficult winter has the potential to set us back a year in our quest to improve the herd in-calf rate to 90% at 12 weeks of mating. This is compounded by the continued presence of late calving cows. These have come as a surprise to us because we were confident that our 6 pregnancy test program would give us accurate expected calving dates for all the cows. During last year no specific recording of bull matings occurred. The lesson for us had been that observation of and recording of bull matings is required to verify pregnancy scan results to confirm pregnancy dates.

Time saving strategies used this year.

Activity	Time saved	Other benefits/costs
Milking all the cows OAD until half the herd had calved	An average of 2 hrs /day for 30 days = 60 hrs	More time for staff to concentrate on calving cows during the busiest time for calving. Less Milk fever Less colostrum to feed to calves
Colostrum, Mastitis, lame and other "sick" cows only milked OAD	1 hr/day for 2 staff for 90 days 30 min/day for 2 staff for 150 days = 330 hrs	Improved staff moral as all the messy cow stuff over and done in the morning. More time to do other jobs in the afternoon before milking. Less chance for hold-ups to reliably get home by 5pm
Feeding all the calves only OAD (Pukawa System)	3 hrs /day for the first 6 weeks and 1 hour /day for the next 6 weeks = 170 hrs	More enthusiasm to do it once properly Done by on farm staff More time in the afternoon to do other jobs. Calves eat more meal
Calves outside on grass after 2 weeks. (once dis-budded and DNA tested)		Better hygiene /few losses Less housing needed Less chance of disease spread Calves encouraged to eat grass sooner.

Lincoln University Dairy Farm [LUDF]

HEIFER SYNCHRONY PROTOCOLS

- 1. All heifers would exceed minimum target weight for age and breed 3 weeks before programme starts.
- 2. Given a worm drench, plus vaccinate and copper bullet as required (plus other minerals if required) 3 weeks prior to synchrony programme.
- 3. All heifers would be grazing on high quality pasture leading up to and through mating.
- 4. Synchrony would be with two PG jabs 10 days apart.
- 5. Timing of synchrony would be such that this mating would occur 5 to 7 days prior to the start of mating of the mature LUDF herd.
- 6. Tail painting occurs at the time of the second PG jab.
- 7. AB Mating occurs on observed heats after 2nd PG jab for next three days.
- 8. Jersey bulls to be run with the heifer mob after AB insemination on the third day at a minimum ratio of 1: 15.
- 9. Jersey bulls remain with mob for 10 weeks with additional bulls to bring ratio up to 1:10 for week 3, 4, 5 of mating.
- 10. 6 8 week after start of mating we pregnancy test (scan and palpate if required) to identify those in-calf to AB.
- 11. Final Pregnancy test (Scan and palpate) at end of April to identify non-pregnant animals for culling.

Getting value out of regrassing.

Graham Kerr (Agriseeds), Adrian van Bysterveldt (Dexcel)

Beliefs on regrassing

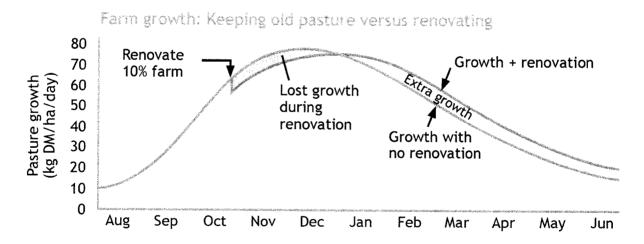

- 1. Most people believe pasture renovation is profitable TRUE It must be, as we renovate pastures every year.
- 2. Most people don't know <u>how</u> profitable their renovation is TRUE
 We believe this is holding back many farms from growing the optimal amount of pasture. Are you renovating enough? Or too much?

We need some estimate of this to make the best decisions.

3. Looking at a pasture is the way to assess it - FALSE

False. It is one way, but not the best way. 'Scruffy' looking pastures sometimes produce well. Good looking pastures – for example this paddock N11 – can still be profitably improved, if we know they're not performing.

Advantage of spring regrassing

In the South Island we can spring sow, so get returns in the same season. Growth lost during renovation is offset by the better autumn production of the new pastures (see graph above).

If you have a high stocking rate and struggle to renovate what you want, consider silage. If you feed silage in spring to achieve strategic renovation, you'll get that DM back in autumn (see graph above). So use new grass (not silage) to extend lactation.

The key to decisions comes from assessing your farms pasture performance.

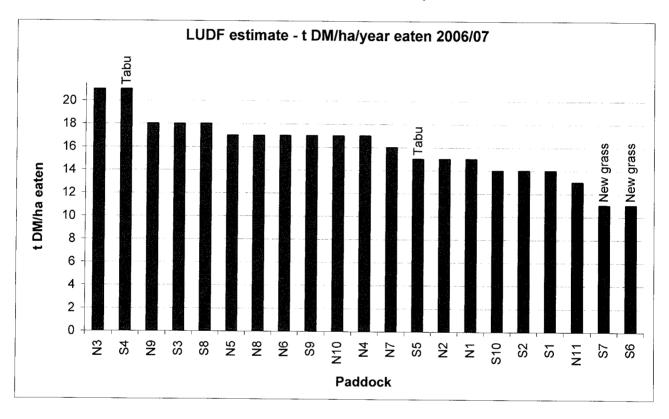

Assessing your farms pasture

We are working through how to estimate a farms individual paddock growth. Note we say <u>estimate</u>, as it's not possible to accurately measure. At the end of the day if we can show the big differences, that will make the money.

Grazing records calculation

We have calculated paddock growth by looking at how many cows grazed in each paddock. This needs corrected for any silage made (extra growth) and silage fed out (as if cows eat silage they eat less grass). Details on how this is done are in appendix one.

The results below show the range of paddock performance. The best paddocks show the farms potential to grow. The worst are identified for possible action.

S6 & S7

The poorest paddocks S6 and S7 were renovated last spring, in a dreadful spring! They were used as a sacrifice area, and during renovation water springs appeared in the back of these very wet paddocks. They had to be sown on two occasions, a month apart. (Since renovation, records show S6 and S7 have grown about 20% above the farm average.)

<u>N11</u>

N11 is the next poorest paddock, targeted for renovation this spring for the end of November. Part of the reason for the poor performance is the area of unsown (old) pasture on the western side. Soil fertility, drainage and irrigation are all good.

There are many paddocks growing 17-18 t DM/ha for the cows. If we get an extra 4 t DM/ha from N11, that's 320 kgMS/ha = \$1900/ha income (at \$6/kgMS) each year.

Cost of renovation will be a around \$1200/ha, about \$600 for the direct cost (drilling, spraying, seed etc) the other half the loss of MS from missing 8 weeks grazing.

RPM pasture cover (farm walk) calculation

S10	19
N11	19
N7	19
S7	18
S6	18

On the LUDF we also take weekly farm walks, to measure cover with the Rising Plate Meter (RPM).

These were converted to paddock growth by:

- RPM cover readings were taken each Tuesday from each paddock, giving cover (kg DM/ha)
- Cover at grazing = last RPM reading + extra days growth (average farm growth rate was used for the extra days growth)
- Residual was estimated when a paddock was grazed.
- Cover at grazing minus residual = gives pasture grown (disappeared).
- Growth from each grazing for each paddock is added up for the season

Comparison

Overall the paddock growth rankings from *Grazing records* and *RPM pasture cover* are very similar (but not identical). Both give the 'big picture' and identify the poorest paddocks.

They both measure slightly different things, and some things still need worked through. For example we believe the *Bealey* tetraploid perennial ryegrass paddocks (S1 and S10) may be under estimated by *Grazing records* analysis, as *Bealey*'s palatability is likely to mean cow intake is higher on these paddocks.

For paddock N7 the RPM figures were lower. Investigation showed the route of the weekly farm walk took in the worst portion of the paddock, effected by grass grub, which was not representative. The route has now been changed.

Where to?

Pasture renovation is an economic investment - provided it is well done, correcting the underlying reasons for poor paddock growth.

To make the best decision on <u>how much</u> renovation we should do, we need to know the performance of individual paddocks. This shows what proportion of the farm is underperforming. We are trying to develop a relatively simple way to do this.

Appendix One: Calculating paddock growth from grazing days

If you don't have all the information below, look at estimating things. An estimate is better than nothing. Remember you are trying to identify the <u>big</u> differences.

- Add up the number of cows in each paddock for a 12-hour grazing. (If they were in that paddock, they were eating pasture.)
- Add in other grazings (sick, colostrums etc)
- Add in any silage made. For this we have assumed a 12 hour grazing day = 8.5 kgDM. E.g. if 8,500 kgDM silage was made off a paddock, that's 1000 grazings. This assumes differences in intake in weather
- Subtract any silage fed out in each paddock. (If cows eat silage they're not eating the grass). If 1700 kgDM of silage were fed that's 200 grazings, given 12 hour grazing day = 8.5 kgDM
- This calculates *Total Grazings*, which needs corrected for varying paddock sizes (*Total Grazings/ha*), which we ranked from top to bottom below.
- We know from back calculation from milk production we eat about 16 tDM/ha across the farm, so can convert Total Grazings/ha to t DM/ha eaten.

LUDF estimate - t DM/ha eaten 2006/2007

Pdk	Milkers grazings (12 hours)	+ Sick, colostrum (grazings)	+ Silage made (grazings)	- silage fed out (grazings)	= Total Grazings	Total Grazing /ha	t DM/ha eaten (assuming 16 t average)

Lincoln University Dairy Farm

Pasture analysis for 2007/08 season - pre grazing cuts

NOTE: We sample the paddocks immediately in front of the milkers, to height of 3.5cm (7 clicks on the rising plate meter)
The yellow entries indicate values that are at extreme or unusual levels.
